FAN7710V
Ballast Control IC for Compact Fluorescent Lamps

Features
- Integrated Half-Bridge MOSFET
- Floating Channel FAN7710V for Bootstrap Operation to +440V
- Low Startup and Operating Current: 120μA, 2.6mA
- Under-Voltage Lockout with 1.8V of Hysteresis
- Adjustable Run Frequency and Preheat Time
- Internal Active ZVS Control
- Internal Protection Function (No Lamp)
- Internal Clamping Zener Diode
- High Accuracy Oscillator
- Soft-Start Functionality

Description
FAN7710V developed using Fairchild’s high-voltage process and system-in-package (SiP) concept, are ballast-control integrated circuits (ICs) for compact fluorescent lamps (CFL). FAN7710V incorporates a preheating / ignition function, controlled by a user-selected external capacitor, to increase lamp life. The FAN7710V detects switch operation after ignition mode through an internal active Zero-Voltage Switching (ZVS) control circuit. This control scheme enables the FAN7710V to detect an open-lamp condition, without the expense of external circuitry, and prevents stress on the MOSFETs. The high-side driver in the FAN7710V has a common-mode noise cancellation circuit that provides robust operation against high-dv/dt noise intrusion.

Applications
- Compact Fluorescent Lamp Ballast

### Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only. $T_A=25^\circ\text{C}$ unless otherwise specified.

1. Under-Voltage Lockout (UVLO) Function

The FAN7710V has UVLO circuits for both high-side and low-side circuits. When VDD reaches VDDH(ST+), UVLO is released and the FAN7710V operates normally. At UVLO condition, FAN7710V consumes little current, noted as IST. Once UVLO is released, FAN7710V operates normally until VDD goes below VDDH(ST-) the UVLO hysteresis. At UVLO condition, all latches that determine the status of the IC are reset. When the IC is in the shutdown mode, the IC can restart by lowering VDD voltage below VDDH(ST-).

FAN7710V has a high-side gate driver circuit. The supply for the high-side driver is applied between VB and VOUT. To protect from malfunction of the driver at low supply voltage between VB and VOUT, there is an additional UVLO circuit between the supply rails. If VB-VOUT is under VHSTH(ST+), the driver holds LOW state to turn off the high-side switch, as shown in Figure 25. As long as VB-VOUT is higher than VHSTH(ST-) after VB-VOUT exceeds VHSTH(ST+), operation of the driver continues.

2. Oscillator

The ballast circuit for a fluorescent lamp is based on the LCC resonant tank and a half-bridge inverter circuit, as shown in Figure 25. To accomplish Zero-Voltage Switching (ZVS) of the half-bridge inverter circuit, the LCC is driven at a higher frequency than its resonant frequency, which is determined by LC, CS, CP, and RL; where RL is the equivalent lamp's impedance.

The transfer function of LCC resonant tank is heavily dependent on the lamp impedance, RL, as illustrated in Figure 26. The oscillator in FAN7710V generates effective driving frequencies to assist lamp ignition and improve lamp life longevity. Accordingly, the oscillation frequency is changed in following sequence:

Preheating Frequency → Ignition Frequency → Normal Running Frequency

Before the lamp is ignited, the lamp impedance is very high. Once the lamp is turned on, the lamp impedance significantly decreases. Since the resonant peak is very high due to the high-resistance of the lamp at the instant of turning on the lamp, the lamp must be driven at higher frequency than the resonant frequency, shown as (A) in Figure 26. In this mode, the current supplied by the inverter mainly flows through CP. CP connects both filaments and makes the current path to ground. As a result, the current warms up the filament for easy ignition. The amount of the current can be adjusted by controlling the oscillation frequency or changing the capacitance of CP. The driving frequency, fPRE, is called preheating frequency and is derived by:

\[ f_{PRE} = 1.6 \times f_{OSC} \]  

After the warm-up, the FAN7710V decreases the frequency, shown as (B) of Figure 26. This action increases the voltage of the lamp and helps the fluorescent lamp ignite. The ignition frequency is described as a function of CPH voltage, as follows:

\[ f_{IG} = \left[ 0.3 \times (5 - V_{CPH}) \right] + 1 \]  \times f_{OSC} \]  

where CP = the voltage of CPH capacitor.

Equation 2 is valid only when VCPH is between 3V and 5V before entering running mode. Once VCPH reaches 5V, the internal latch records the exit from ignition mode. Unless VDD is below VDDH(ST-), the preheating and ignition modes appear only during lamp-start transition.

Finally, the lamp is driven at a fixed frequency by an external resistor, RT, shown as (C) in Figure 26. If VDD is higher than VDDH(ST+) and UVLO is released, the voltage of the RT pin is regulated to 4V. This voltage adjusts the oscillator's control current according to the resistance of RT. Because this current and an internal capacitor set the oscillation frequency, the FAN7710V does not need any external capacitors.

The proposed oscillation characteristic is given by:

\[ f_{OSC} = \frac{4 \times 10^9}{RT} \]  

Even in the active ZVS mode, shown as (D) in Figure 26, the oscillation frequency is not changed. The dead time is varied according to the resonant tank characteristic.
3. Operation Modes

FAN7710V has four operation modes: (A) preheating mode, (B) ignition mode, (C) active ZVS mode and (D) shutdown mode; all depicted in Figure 27. The modes are automatically selected by the voltage of CPH capacitor shown in Figure 27. In modes (A) and (B), the CPH acts as a timer to determine the preheating and ignition times. After preheating and ignition modes, the role of the CPH is changed to stabilize the active ZVS control circuit. In this mode, the dead time of the inverter is selected by the voltage of CPH. Only when in active ZVS mode is it possible to shut off the whole system using the CPH pin. Pulling the CPH pin below 2V in active ZVS mode causes the FAN7710V series to enter shutdown mode. In shutdown mode, all active operation is stopped except UVLO and some bias circuitry. The shutdown mode is triggered by the external CPH control or the active ZVS circuit. The active ZVS circuit automatically detects lamp removal (open-lamp condition) and decreases CPH voltage below 2V to protect the inverter switches from damage.

3.1 Preheating Mode (t0–t1)

When V_{DD} exceeds V_{DDTH(ST+)}, the FAN7710V series starts operation. At this time, an internal current source (I_{PH}) charges CPH. CPH voltage increases from 0V to 3V in preheating mode. Accordingly, the oscillation frequency follows Equation 4. In this mode, the lamp is not ignited, but warmed up for easy ignition. The preheating time depends on the size of CPH:

\[ t_{\text{preheat}} = \frac{3 \times \text{CPH}}{I_{\text{PH}}} \text{[seconds]} \] (4)

According to the preheating process, the voltage across the lamp to ignite is reduced and the lifetime of the lamp is increased. In this mode, the dead time is fixed at its maximum value.

3.2 Ignition Mode (t1–t2)

When the CPH voltage exceeds 3V, the internal current source charging CPH is increased about six times larger than I_{PH}, noted as I_{IG}, causing rapid increase in CPH voltage. The internal oscillator decreases the oscillation frequency from f_{PRE} to f_{OSC} as CPH voltage increases. As depicted in Figure 27, lowering the frequency increases the voltage across the lamp. Finally, the lamp ignites. Ignition mode is when CPH voltage is between 3V and 5V. Once CPH voltage reaches 5V, the FAN7710V does not return to ignition mode, even if the CPH voltage is in that range, until the FAN7710V restarts from below V_{DDTH(ST-)}. Since the ignition mode continues when CPH is from 3V to 5V, the ignition time is given by:

\[ t_{\text{ignition}} = \frac{2 \times \text{CPH}}{I_{\text{IG}}} \text{[seconds]} \] (5)

In this mode, dead time varies according to the CPH voltage.

3.3 Running Mode and Active Zero-Voltage Switching (AZVS) Mode (t2–)

When CPH voltage exceeds 5V, the operating frequency is fixed to f_{OSC} by R_{T}. However, active ZVS operation is not activated until CPH reaches ~6V. Only the FAN7710V prepares for active ZVS operation from the instant CPH exceeds 5V during t2 to t3. When CPH becomes higher than ~6V at t3, the active ZVS operation is activated. To determine the switching condition, FAN7710V detects the transition time of the output (VS pin) of the inverter by using the VB pin. From the output-transition information, FAN7710V controls the dead time to meet the ZVS condition. If ZVS is satisfied, the FAN7710V slightly increases the CPH voltage to reduce the dead time and to find optimal dead time, which increases the efficiency and decreases the thermal dissipation and EMI of the inverter switches. If ZVS fails, the FAN7710V decreases CPH voltage to increase the dead time. CPH voltage is adjusted to meet optimal ZVS operation. During the active ZVS mode, the amount of the charging / discharging current is the same as I_{PH}. Figure 28 depicts normal operation waveforms.
3.4 Shutdown Mode

If the voltage of capacitor CPH is decreased below ~2.1V by an external application circuit or internal protection circuit, the IC enters shutdown mode. Once the IC enters shutdown mode, this status continues until an internal latch is reset by decreasing VDD below VDDTH(ST-). Figure 29 shows an example of external shutdown control circuit.

The amount of the CPH charging current is the same as \( I_{\text{IH}} \), making it possible to shut off the IC using a small signal transistor. Only the FAN7710V provides active ZVS operation by controlling the dead time according to the voltage of CPH. If ZVS fails, even at the maximum dead time, FAN7710V stops driving the inverter.

The FAN7710V thermal shutdown circuit senses the junction temperature of the IC. If the temperature exceeds ~160°C, the thermal shutdown circuit stops operation of the FAN7710V.

The current usages of shutdown mode and under-voltage lockout status are different. In shutdown mode, some circuit blocks, such as bias circuits, are kept alive. Therefore, the current consumption is slightly higher than during under-voltage lockout.

4. Automatic Open-Lamp Detection

The FAN7710V can automatically detect an open-lamp condition. When the lamp is opened, the resonant tank fails to make a closed-loop to the ground, as shown in Figure 30. The supplied current from the OUT pin is used to charge and discharge the charge pump capacitor, \( C_p \). Since the open-lamp condition means resonant tank absence, it is impossible to meet ZVS condition. In this condition, the power dissipation of the FAN7710V, due to capacitive load drive, is estimated as:

\[
P_{\text{dissipation}} = \frac{1}{2} \times C_p \times V_{\text{DC}}^2 \times f \quad [W]
\]

where \( f \) is driving frequency and \( V_{\text{DC}} \) is DC-link voltage.

Assuming that \( C_p \), \( V_{\text{DC}} \), and \( f \) are 1nF, 311V, and 50kHz, respectively; the power dissipation reaches about 2.4W and the temperature of is increased rapidly. If no protection is provided, the IC can be damaged by the thermal attack. Note that a hard-switching condition during the capacitive-load drive causes EMI.

Figure 31 illustrates the waveforms during the open-lamp condition. In this condition, the charging and discharging current of \( C_p \) is directly determined by FAN7710V and considered hard-switching condition. The FAN7710V tries to meet ZVS condition by decreasing CPH voltage to increase dead time. If ZVS fails and CPH goes below 2V, even though the dead time reaches its maximum value, FAN7710V shuts off the IC to protect against damage. To restart FAN7710V, VDD must be below VDDTH(ST-) to reset an internal latch circuit, which remembers the status of the IC.

5. Power Supply
When $V_{DD}$ is lower than $V_{DDTH(ST+)}$, it consumes very little current, $I_{ST}$, making it possible to supply current to the $V_{DD}$ pin using a resistor with high resistance ($R_{start}$ in Figure 32). Once UVLO is released, the current consumption is increased and whole circuit is operated, which requires additional power supply for stable operation. The supply must deliver at least several mA. A charge pump circuit is a cost-effective method to create an additional power supply and allows $C_{P}$ to be used to reduce the EMI.

![Figure 32. Local Power Supply for $V_{DD}$ Using a Charge-Pump Circuit](image)

As presented in Figure 32, when OUT is HIGH, the inductor current and $C_{CP}$ create an output transition with the slope of $dv/dt$. The rising edge of OUT charges $C_{CP}$. At that time, the current that flows through $C_{CP}$ is:

$$I = C_{CP} \times \frac{dv}{dt}$$  \hspace{1cm} (7)

This current flows along path 1 in Figure 32. It charges $C_{VDD}$, which is a bypass capacitor to reduce the noise on the supply rail. If $C_{VDD}$ is charged over the threshold voltage of the internal shunt regulator, the shunt regulator turns on and regulates $V_{DD}$ with the trigger voltage.

When OUT is changing from HIGH to LOW state, $C_{CP}$ is discharged through $D_{p2}$, shown as path 2 in Figure 32. These charging/discharging operations are continued until FAN7710V is halted by shutdown operation. The charging current, $I$, must be large enough to supply the operating current of FAN7710V.

The supply for the high-side gate driver is provided by the boot-strap technique, as illustrated in Figure 33. When the low-side MOSFET connected between OUT and PGND pins is turned on, the charging current for $V_{B}$ flows through $D_{a}$. Every low OUT gives the chance to charge the $C_{B}$. Therefore, $C_{B}$ voltage builds up only when FAN7710V operates normally.

When OUT goes HIGH, the diode $D_{a}$ is reverse-biased and $C_{B}$ supplies the current to the high-side driver. At this time, since $C_{B}$ discharges, $V_{B}-V_{OUT}$ voltage decreases. If $V_{B}-V_{OUT}$ goes below $V_{HSTH(ST-)}$, the high-side driver cannot operate due to the high-side UVLO protection circuit. $C_{B}$ must be chosen to be large enough not to fall into UVLO range, due to the discharge during a half of the oscillation period, especially when the high-side MOSFET is turned on.

![Figure 33. Implementation of Floating Power Supply Using the Bootstrap Method](image)
Design Guide

1. Startup Circuit

The startup current (I_{ST}) has to be supplied to the IC through the startup resistor, R_{start}. Once operation starts, the power is supplied by the charge pump circuit. To reduce the power dissipation in R_{start}, select R_{start} as high as possible, considering the current requirements at startup. For 220VAC power, the rectified voltage by the full-wave rectifier makes DC voltage, as shown in Equation 8. The voltage contains lots of AC component, due to poor regulation characteristic of the simple full-wave rectifier:

\[ V_{DC} = \sqrt{2} \times 220[V] \equiv 311[V] \]  

(8)

Considering the selected parameters, R_{start} must satisfy the following equation:

\[ \frac{V_{DC} - V_{DDTH(ST+)}}{R_{start}} > I_{ST} \]  

(9)

From Equation 9, R_{start} is selected as:

\[ \frac{V_{DC} - V_{DDTH(ST+)}}{I_{ST}} > R_{start} \]  

(10)

Note that if choosing the maximum R_{start}, it takes a long time for VDD to reach VDDTH(ST+). Considering VDD rising time, R_{start} must be selected as shown in Figure 34. Another important concern for choosing R_{start} is the available power rating of R_{start}. To use a commercially available, low-cost 1/4Ω resistor, R_{start} must obey the following rule:

\[ \frac{(V_{DC} - V_{CL})^2}{I_{ST}} < 4[W] \]  

(11)

Assuming V_{DC}=311V and V_{CL}=15V, the minimum resistance of R_{start} is about 350kΩ.

When the IC operates in shutdown mode due to thermal protection, open-lamp protection, or hard-switching protection; the IC consumes shutdown current, I_{SD}, which is larger than I_{ST}. To prevent restart during this mode, R_{start} must be selected to cover I_{SD} current consumption. The following equation must be satisfied:

\[ \frac{V_{DC} - V_{DDTH(ST+)}}{I_{SD}} > R_{start} \]  

(12)

From Equations 10 - 12; it is possible to select R_{start}:

1) For safe startup without restart in shutdown mode:

\[ 4(V_{DC} - V_{CL})^2 < R_{start} < \frac{V_{DC} - V_{DDTH(ST+)}}{I_{SD}} \]  

(13)

2) For safe startup with restart from shutdown mode:

\[ \frac{V_{DC} - V_{DDTH(ST+)}}{I_{SD}} < R_{start} < \frac{V_{DC} - V_{DDTH(ST+)}}{I_{ST}} \]  

(14)

If R_{start} meets Equation 14, restart operation is possible. However, it is not recommended to choose R_{start} at that range since VDD rising time could be long and increase the lamp’s turn-on delay time, as depicted in Figure 34.

![Figure 34. VDD Build-up](image)

Figure 35 shows the equivalent circuit for estimating t_{start}. From the circuit analysis, VDD variation versus time is given by:

\[ V_{DD}(t) = (V_{DC} - R_{start} \cdot I_{ST}) \left(1 - e^{-t/(R_{start} \cdot C_{VDD})}\right) \]  

(15)

where C_{VDD} is the total capacitance of the bypass capacitors connected between VDD and GND.

From Equation 15, it is possible to calculate t_{start} by substituting V_{DD(t)} with V_{DDTH(ST+)}:

\[ t_{start} = R_{start} \cdot C_{VDD} \cdot \ln\frac{V_{DC} - R_{start} \cdot I_{ST} - V_{DDTH(ST+)}}{V_{DD} - R_{start} \cdot I_{ST}} \]  

(16)

In general, Equation 16 can be simplified as:

\[ t_{start} = \frac{R_{start} \cdot C_{VDD} \cdot V_{DDTH(ST+)}}{V_{DC} - R_{start} \cdot I_{ST} - V_{DDTH(ST+)}} \]  

(17)

Accordingly, t_{start} can be controlled by adjusting the value of R_{start} and C_{VDD}. For example, if V_{DC}=311V, R_{start}=560kΩ, C_{VDD}=10µF, I_{st}=120µA, and V_{DDTH(ST+)}=13.5V; t_{start} is about 0.33s.

![Figure 35. Equivalent Circuit During Startup](image)
2. Current Supplied by Charge Pump

For the IC supply, the charge pump method is used in Figure 36. Since \( C_{CP} \) is connected to the half-bridge output, the supplied current by \( C_{CP} \) to the IC is determined by the output voltage of the half-bridge.

When the half-bridge output shows rising slope, \( C_{CP} \) is charged and the charging current is supplied to the IC. The current can be estimated as:

\[
I = C_{CP} \frac{dV}{dt} = C_{CP} \frac{V_D}{DT}
\]

(18)

where DT is the dead time and \( dV/dt \) is the voltage variation of the half-bridge output.

When the half-bridge shows falling slope, \( C_{CP} \) is discharged through \( D_{p2} \). Total supplied current, \( I_{total} \), to the IC during switching period, \( t \), is:

\[
I_{total} = I \cdot DT = C_{CP} \cdot V_D
\]

(19)

From Equation 19, the average current, \( I_{avg} \), supplied to the IC is obtained by:

\[
I_{avg} = \frac{I_{total}}{t} = \frac{C_{CP} \cdot V_D}{t} = C_{CP} \cdot V_D \cdot f
\]

(20)

For stable operation, \( I_{avg} \) must be higher than the required current. If \( I_{avg} \) exceeds the required current, the residual current flows through the shunt regulator implemented on the chip, which can cause unwanted heat generation. Therefore, \( C_{CP} \) must be selected considering stable operation and thermal generation.

For example, if \( C_{CP}=0.5\,\text{nF} \), \( V_D=311\,\text{V} \), and \( f=50\,\text{kHz} \), \( I_{avg} \) is \( \sim7.8\,\text{mA} \); it is enough current for stable operation.

3. Lamp Turn-On Time

The turn-on time of the lamp is determined by supply build-up time \( t_{start} \), preheating time, and ignition time; where \( t_{start} \) has been obtained by Equation 17. When the IC's supply voltage exceeds \( V_{DDH(ST+)} \) after turn-on or restart, the IC operates in preheating mode. This operation continues until \( CPH \) pin's voltage reaches \( \sim3\,\text{V} \). In this mode, \( CPH \) capacitor is charged by \( I_{PH} \) current, as depicted in Figure 37. The preheating time is achieved by calculating:

\[
t_{preheat} = \frac{3 \times CPH}{I_{PH}} \text{[seconds]}
\]

(21)

The preheating time is related to lamp life (especially filament). Therefore, the characteristics of a given lamp should be considered when choosing the time.

For stable operation, \( I_{avg} \) must be higher than the required current. If \( I_{avg} \) exceeds the required current, the residual current flows through the shunt regulator implemented on the chip, which can cause unwanted heat generation. Therefore, \( C_{CP} \) must be selected considering stable operation and thermal generation.

For example, if \( V_D=311\,\text{V} \), and \( f=50\,\text{kHz} \), \( I_{avg} \) is \( \sim7.8\,\text{mA} \); it is enough current for stable operation.

Compared to the preheating time, it is almost impossible to exactly predict the ignition time, whose definition is the time from the end of the preheating time to ignition. In general, the lamp ignites during the ignition mode. Therefore, assume that the maximum ignition time is the same as the duration of ignition mode, from \( 3\,\text{V} \) until \( CPH \) reaches \( 5\,\text{V} \). Thus, ignition time can be defined as:

\[
I_{ignition} = (5 - 3) \frac{CPH}{I_{IG}} = 2 \frac{CPH}{I_{IG}}
\]

(22)

Note that in ignition mode, \( CPH \) is charged by \( I_{IG} \), which is six times larger than \( I_{PH} \). Consequently, total turn-on time is approximately \( V_D \) Build-Time + Preheating Time + Ignition Time, or:

\[
I_{ignition} = (5 - 3) \frac{CPH}{I_{IG}} = 2 \frac{CPH}{I_{IG}} \text{[seconds]}
\]

**Notes:**

3. Refer to the Typical Application Circuit for 3U type CFL lamp provided in Figure 1.
4. Refer to the Design Guide startup circuit in Figure 35. Due to reducing power loss on the startup resistor (R1) for high-efficiency systems, it is possible to use a higher resistor value than recommended. In this case, the IC doesn’t reliably keep SD (shutdown) state for protection. Carefully select the startup resistor (R1) or use the recommended value (470k) to sufficiently supply shutdown current (ISD) and startup current (IST).
5. Normally, this component could be changed to a normal miller capacitor to increase system reliability instead of the electrolytic capacitor with high temperature characteristics.
6. Temperature dependency of the capacitance is important to prevent destruction of the IC. Some capacitors show capacitance degradation in high temperatures and cannot guarantee enough preheating time to safely ignite the lamp during the ignition period at high temperatures. If the lamp does not ignite during the ignition period, the IC cannot guarantee ZVS operation, Thus, the peak current of the switching devices can be increased above allowable peak current level of the switching devices. Especially in high temperatures, the switching device can be easily destroyed. Consequently, CPH capacitor (C5) must be large enough to warm the filaments of the lamp up over the concerning temperature range.
7. Consider the components (L2, C6, C7) of resonant tank variation over the concerning temperature range. Normally, these components would be changed toward increasing inductance and capacitance in high temperature. That means that the resonant frequency is decreased. In the lower resonant frequency condition, the preheating current reduces, so the resonant tank cannot supply enough to preheat the filaments before lamp turn on. If the preheating current is insufficient, the ignition voltage / current is increased. Check the ignition current in high temperature: the current capacity of internal MOSFETs on IC must be larger than ignition current.

DISCLAIMER
FAIRCHILD SEMICONDUCTOR RESERVES THE RIGHT TO MAKE CHANGES WITHOUT FURTHER NOTICE TO ANY PRODUCTS HEREIN TO IMPROVE RELIABILITY, FUNCTION, OR DESIGN. FAIRCHILD DOES NOT ASSUME ANY LIABILITY ARISING OUT OF THE APPLICATION OR USE OF ANY PRODUCT OR CIRCUIT DESCRIBED HEREIN; NEITHER DOES IT CONVEY ANY LICENSE UNDER ITS PATENT RIGHTS, NOR THE RIGHTS OF OTHERS. THESE SPECIFICATIONS DO NOT EXPAND THE TERMS OF FAIRCHILD’S WORLDWIDE TERMS AND CONDITIONS, SPECIFICALLY THE WARRANTY THEREIN. WHICH COVERS THESE PRODUCTS.

LIFE SUPPORT POLICY
FAIRCHILD’S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF FAIRCHILD SEMICONDUCTOR CORPORATION.

As used herein:
1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body or (b) support or sustain life, and (c) whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.

2. A critical component in any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

ANTI-COUNTERFEITING POLICY
Fairchild Semiconductor Corporation’s Anti-Counterfeiting Policy. Fairchild’s Anti-Counterfeiting Policy is also stated on our external website, www.fairchildsemi.com, under Sales Support.

Countering semiconductor parts is a growing problem in the industry. All manufacturers of semiconductor products are experiencing counterfeiting of their parts. Customers who inadvertently purchase counterfeit parts experience many problems such as loss of brand reputation, substandard performance, failed applications, and increased cost of production and manufacturing delays. Fairchild is taking strong measures to protect ourselves and our customers from the proliferation of counterfeit parts.

Fairchild strongly encourages customers to purchase Fairchild parts either directly from Fairchild or from Authorized Fairchild Distributors who are listed by country on our website cited above. Products purchased through unauthorized channels are at risk of being counterfeit. All customers should check the part number and lot number in the Fairchild database. Fairchild product is distributed through a network of independent distributors. For assistance with ordering Fairchild parts, please contact a Fairchild sales office.
