

NCV6336

Step Down Converter - Transient Load Helper, Configurable

5.0 A

The NCV6336 is a synchronous buck converter optimized to supply the different sub systems of portable applications powered by one cell Li-Ion or three cell Alkaline/NiCd/NiMH batteries. The device is able to deliver up to 5.0 A, with programmable output voltage from 0.6 V to 1.4 V. It can share the same output rail with another DC-to-DC converter and works as a transient load helper. Operation at a 2.74 MHz switching frequency allows the use of small components. Synchronous rectification and automatic PWM/PFM transitions improve overall solution efficiency. The NCV6336 is in a space saving, low profile 2.0 x 1.6 mm CSP-20 package.

Features

- Input Voltage Range from 2.3 V to 5.5 V: Battery and 5 V Rail Powered Applications
- Programmable Output Voltage: 0.6 V to 1.4 V in 6.25 mV Steps
- 2.74 MHz Switching Frequency with On Chip Oscillator
- Uses 330 nH Inductor and 47 μ F Capacitors for Optimized Footprint and Solution Thickness
- PFM/PWM Operation for Optimum Increased Efficiency
- Low 35 μ A Quiescent Current
- I²C Control Interface with Interrupt and Dynamic Voltage Scaling Support
- Enable Pins, Power Good / Fail Signaling
- Thermal Protections and Temperature Management
- Transient Load Helper: Share the Same Rail with Another Rail
- Small 2.0 x 1.6 mm / 0.4 mm Pitch CSP Package
- NCV Prefix for Automotive and Other Applications Requiring Unique Site and Control Change Requirements; AEC-Q100 Qualified and PPAP Capable
- These Devices are Pb-Free, Halogen Free/BFR Free and are RoHS Compliant

Typical Applications

- Smartphones
- Webtablets

PIN FUNCTION DESCRIPTION

Pin	Name	Type	Description
-----	------	------	-------------

REFERENCE

D1	AVIN	Analog Input	Analog Supply. This pin is the device analog and digital supply. Could be connected directly to the VIN plane just next to the 4.7 μ F PVIN capacitor or to a dedicated 1.0 μ F ceramic capacitor.
B4	AGND	Analog Ground	Analog Ground. Analog and digital modules ground. Must be connected to the system ground.

CONTROL AND SERIAL INTERFACE

A2	EN	Digital Input	Enable Control. Active high will enable the part. There is an internal pull down resistor on this pin.
A1	VSEL	Digital Input	Output voltage / Mode Selection. The level determines which of two programmable configurations to utilize (operating mode / output voltage). There is an internal pull down resistor on this pin; could be left open if not used.
A3	SCL	Digital Input	I²C interface Clock line. There is an internal pull down resistor on this pin; could be left open if not used
B1	SDA	Digital Input/Output	I²C interface Bi-directional Data line. There is an internal pull down resistor on this pin; could be left open if not used
B3	PGND PG	Digital Output Analog Ground	Power Good open drain output. If not used has to be connected to ground plane
B2	PGND INTB	Digital Output Analog Ground	Interrupt open drain output. If not used has to be connected to ground plane

DC to DC CONVERTER

D2, E1, E2	PVIN	Power Input	Switch Supply. These pins must be decoupled to ground by a 4.7 μ F ceramic capacitor. It should be placed as close as possible to these pins. All pins must be used with short heavy connections.
D3, D4, E3, E4	SW	Power Output	Switch Node. These pins supply drive power to the inductor. Typical application uses 0.33 μ H inductor; refer to application section for more information. All pins must be used with short heavy connections.
C1, C2, C3, C4	PGND	Power Ground	Switch Ground. This pin is the power ground and carries the high switching current. High quality ground must be provided to prevent noise spikes. To avoid high-density current flow in a limited PCB track, a local ground plane that connects all PGND pins together is recommended. Analog and power grounds should only be connected together in one location with a trace.
A4	FB	Analog Input	Feedback Voltage input. Must be connected to the output capacitor positive terminal with a trace, not to a plane. This is the positive input to the error amplifier.

MAXIMUM RATINGS

Rating	Symbol	Value	Unit
Analog and power pins: AVIN, PVIN, SW, PG, INTB, FB (Note 1)	V _A	-0.3 to + 6.0	V
Digital pins: SCL, SDA, EN, VSEL, Pin: Input Voltage Input Current	V _{DG} I _{DG}	-0.3 to V _A + 0.3 ≤ 6.0 10	V mA
Human Body Model (HBM) ESD Rating (Note 2)	ESD HBM	2500	V
Charged Device Model (CDM) ESD Rating (Note 2)	ESD CBM	1250	V
Latch Up Current: (Note 3) Digital Pins All Other Pins	I _{LU}	10 100	mA
Storage Temperature Range	T _{STG}	-65 to +150	°C
Maximum Junction Temperature	T _{JMAX}	-40 to +150	°C
Moisture Sensitivity (Note 4)	MSL	Level 1	

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

1. Refer to ELECTRICAL CHARACTERISTICS, RECOMMENDED OPERATING RANGES and/or APPLICATION INFORMATION for Safe Operating parameters.
2. This device series contains ESD protection and passes the following ratings:
Human Body Model (HBM) ± 2.5 kV per JEDEC standard: JESD22-A114.
Charged Device Model (CDM) ± 1250 V per JEDEC standard: JESD22-C101 Class IV
3. Latch up Current per JEDEC standard: JESD78 class II.
4. Moisture Sensitivity Level (MSL): 1 per IPC/JEDEC standard: J-STD-020A.

OPERATING CONDITIONS

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
AV _{IN} , PV _{IN}	Power Supply		2.3		5.5	V
T _A	Ambient Temperature Range		-40	25	+125	°C
T _J	Junction Temperature Range (Note 6)		-40	25	+125	°C
R _{θJA}	Thermal Resistance Junction to Ambient (Note 7)	CSP-20 on Demo-board	-	55	-	°C/W
P _D	Power Dissipation Rating (Note 8)	T _A ≤ 85°C	-	727	-	mW
P _D	Power Dissipation Rating (Note 8)	T _A = 65°C	-	1090	-	mW
L	Inductor for DC to DC converter (Note 5)		0.26	0.33	0.56	μH
Co	Output Capacitor for DC to DC Converter (Note 5)		30	-	150	μF
Cin	Input Capacitor for DC to DC Converter (Note 5)		4.7	-	-	μF

Functional operation above the stresses listed in the Recommended Operating Ranges is not implied. Extended exposure to stresses beyond the Recommended Operating Ranges limits may affect device reliability.

5. Including de-ratings (Refer to the Application Information section of this document for further details)
6. The thermal shutdown set to 150°C (typical) avoids potential irreversible damage on the device due to power dissipation.
7. The R_{θJA} is dependent of the PCB heat dissipation. The board used to drive this data was a NCP6336EVB board. It is a multilayer board with 1-ounce internal power and ground planes and 2-1 ounce copper traces on top and bottom of the board.
8. The maximum power dissipation (P_D) is dependent by input voltage, maximum output current and external components selected.

$$R_{\theta JA} = \frac{125 - T_A}{P_D}$$

DETAILED OPERATING DESCRIPTION

Detailed Descriptions

The NCV6336 is voltage mode stand-alone synchronous DC to DC converter optimized to supply different sub systems of portable applications powered by one cell Li-Ion or three cells Alkaline/NiCd/NiMh. The IC can deliver up to 5 A at an I²C selectable voltage ranging from 0.6 V to 1.5 V. It can share the same output rail with another DC to DC converter and works as a transient load helper without sinking current on shared rail. A 2.74 MHz switching frequency allows the use of smaller output filter components. Synchronous rectification and automatic PWM/PFM transitions improve overall solution efficiency. Forced PWM is also configurable. Operating modes, configuration, and output power can be easily selected either by using digital I/O pins or by programming a set of registers using an I²C compatible interface capable of operation up to 3.4 MHz. Default I²C settings are factory programmable.

DC to DC Converter Operation

The converter is a synchronous rectifier type with both high side and low side integrated switches. Neither external transistor nor diodes are required for NCV6336 operation. Feedback and compensation network are also fully integrated. The converter can operate in two different modes: PWM and PFM. The transition between PWM/PFM modes can occur automatically or the switcher can be placed in forced PWM mode by I²C programming (PWMVSEL0 / PWMVSEL1 bits of COMMAND register).

PWM (Pulse Width Modulation) Operating Mode

In medium and high load conditions, NCV6336 operates in PWM mode from a fixed clock and adapts its duty cycle to regulate the desired output voltage. In this mode, the inductor current is in CCM (Continuous Current Mode) and the voltage is regulated by PWM. The internal N-MOSFET switch operates as synchronous rectifier and is driven complementary to the P-MOSFET switch. In CCM, the lower switch (N-MOSFET) in a synchronous converter provides a lower voltage drop than the diode in an asynchronous converter, which provides less loss and higher efficiency.

PFM (Pulse Frequency Modulation) Operating Mode

In order to save power and improve efficiency at low loads the NCV6336 operates in PFM mode as the inductor current drops into DCM (Discontinuous Current Mode). The upper FET on time is kept constant and the switching frequency is variable. Output voltage is regulated by varying the switching frequency which becomes proportional to loading current. As it does in PWM mode, the internal N-MOSFET operates as synchronous rectifier after each P-MOSFET on-pulse. When load increases and current in inductor becomes continuous again, the controller automatically turns back to PWM mode.

Forced PWM

The NCV6336 can be programmed to only use PWM and disable the transition to PFM if so desired.

Output Stage

NCV6336 is a 3.5 A to 5.0 A output current capable integrated DC to DC converter. To supply such a high current, the internal MOSFETs need to be large.

Inductor Peak Current Limitation

During normal operation, peak current limitation will monitor and limit the current through the inductor. This current limitation is particularly useful when size and/or height constrain inductor power. The user can select peak current to keep inductor within its specifications. The peak current can be set by writing IPEAK[1..0] bits in LIMCONF register.

Table 1. IPEAK VALUES

IPEAK[1..0]	Inductor Peak Current (A)
00	5.2 – for 3.5 output current
01	5.8 – for 4.0 output current
10	6.2 – for 4.5 output current
11	6.8 – for 5.0 output current

Output Voltage

Output voltage is set internally by integrated resistor bridge and error amplifier that drives the PWM/PFM controller. No extra component is needed to set output voltage. However, writing in the VoutVSEL0[6..0] bits of the PROGVSEL0 register or VoutVSEL1[6..0] bits of the PROGVSEL1 register will change settings. Output voltage level can be programmed in the 0.6 V to 1.40 V range by 6.25 mV steps.

The VSEL pin and VSELGT bit will determine which register between PROGVSEL0 and PROGVSEL1 will set the output voltage.

- If VSELGT = 1 AND VSEL=0 → Output voltage is set by VoutVSEL0[6..0] bits (PROGVSEL0 register)
- Else → Output voltage is set by VoutVSEL1[6..0] bits (PROGVSEL1 register)

Under Voltage Lock Out (UVLO)

NCV6336 core does not operate for voltages below the Under Voltage Lock Out (UVLO) level. Below UVLO threshold, all internal circuitry (both analog and digital) is held in reset.

NCV6336 operation is guaranteed down to VUVLO when battery voltage is dropping off. To avoid erratic on / off behavior, a maximum 200 mV hysteresis is implemented. Restart is guaranteed at 2.5 V when VBAT voltage is recovering or rising.

Thermal Management

Thermal Shut Down (TSD)

The thermal capability of IC can be exceeded due to step down converter output stage power level. A thermal protection circuitry is therefore implemented to prevent the IC from damage. This protection circuitry is only activated when the core is in active mode (output voltage is turned on). During thermal shut down, output voltage is turned off.

When NCV6336 returns from thermal shutdown, it can re-start in 2 different configurations depending on REARM bit in the LIMCONF register (see register description section):

- If REARM = 0 then NCV6336 does not re-start after TSD. To restart, an EN pin toggle is required.
- If REARM = 1, NCV6336 re-starts with register values set prior to thermal shutdown.

A Thermal shut down interrupt is raised upon this event.

Thermal shut down threshold is set at 150°C (typical) when the die temperature increases and, in order to avoid erratic on / off behavior, a 30°C hysteresis is implemented. After a typical 150°C thermal shut down, NCV6336 will resume to normal operation when the die temperature cools to 120°C.

Thermal Warnings

In addition to the TSD, the die temperature monitoring will flag potential die over temperature. A thermal warning and thermal pre-warning sensor and interrupts are implemented. These can inform the processor that NCV6336 is closed to its thermal shutdown, so preventive measures to cool down die temperature can be taken by software.

The Warning threshold is set by hardware to 135°C typical when the die temperature increases. The Pre-Warning threshold is set by default to 105°C, but can be changed by user by setting the TPWTH[1..0] bits in the LIMCONF register.

Active Output Discharge

To make sure that no residual voltage remains in the power supply rail when disabled, an active discharge path can ground the NCV6336 output voltage.

For maximum flexibility, this feature can be easily disabled or enabled with DISCHG bit in PGOOD register. By default the discharge path is enabled.

However the discharged path is activated during the first 100 µs after battery insertion.

Enabling

The EN pin controls NCV6336 start up. EN pin Low to High transition starts the power up sequencer. If EN is made low, the DC to DC converter is turned off and device enters:

- In Sleep Mode if Sleep_Mode I²C bit is high or VSEL is high,
- In Off Mode if Sleep_Mode I²C bit and VSEL are low.

When EN pin is set to a high level, the DC to DC converter can be enabled / disabled by writing the ENVSEL0 or ENVSEL1 bit of the PROGVSEL0 and PROGVSEL1 registers: If ENx I²C bit is high, DC to DC converter is activated, If ENx I²C is low the DC to DC converter is turned off and device enters in Sleep Mode

A built in pull down resistor disables the device when this pin is left unconnected or not driven. EN pin activity does not generate any digital reset.

Power Up Sequence (PUS)

In order to power up the circuit, the input voltage AVIN has to rise above the VUVLO threshold. This triggers the internal core circuitry power up which is the “Wake Up Time” (including “Bias Time”).

This delay is internal and cannot be bypassed. EN pin transition within this delay corresponds to the “Initial power up sequence” (IPUS):

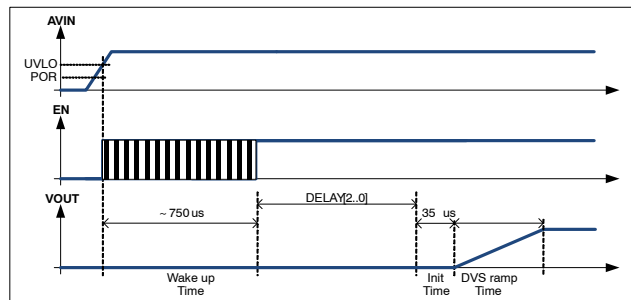

Figure 33. Initial Power Up Sequence

In addition a user programmable delay will also take place between end of Core circuitry turn on (Wake Up Time and Bias Time) and Init time: The DELAY[2..0] bits of TIME register will set this user programmable delay with a 2.2 ms resolution. With default delay of 0 ms, the NCV6336 IPUS takes roughly 900 µs, means DC to DC converter output voltage will be ready within 1 ms.

The power up output voltage is defined by VSEL state.

NOTE: During the Wake Up time, the I²C interface is not active. Any I²C request to the IC during this time period will result in a NACK reply.

Normal, Quick and Fast Power Up Sequence

The previous description applies only when the EN transitions during the internal core circuitry power up (Wake up and calibration time). Otherwise 3 different cases are possible:

- Enabling the part by setting EN pin from Off Mode will result in “Normal power up sequence” (NPUS, with DELAY;[2..0]).
- Enabling the part by setting EN pin from Sleep Mode will result in “Quick power up sequence” (QPUS, with DELAY;[2..0]).

- Enabling the DC to DC converter, whereas EN is already high, either by setting ENVSEL0 or ENVSEL1 bits or by VSEL pin transition will result in “Fast power up sequence” (FPUS, without DELAY[2..0]). Sleep mode is when VSEL is high and EN low, or when Sleep_Mode I²C bit is set and EN is low, or finally when DC to DC converter is off and EN high.

Figure 34. Normal Power Up Sequence

Figure 35. Quick Power Up Sequence

Figure 36. Fast Power Up Sequence

In addition the delay set in DELAY[2..0] bits in TIME register will apply only for the EN pins turn ON sequence (NPUS and QPUS).

The power up output voltage is defined by VSEL state.

Note that the sleep mode needs about 150 μs to be established.

DC to DC Converter Shut Down

When shutting down the device, no shut down sequence is required. Output voltage is disabled and, depending on the DISCHG bit state of PGOOD register, output may be discharged.

DC to DC converter shutdown is initiated by either grounding the EN pin (Hardware Shutdown) or, depending on the VSEL internal signal level, by clearing the ENVSEL0 or ENVSEL1 bits (Software shutdown) in PROGVSEL0 or PROGVSEL1 registers.

In hardware shutdown (EN = 0), the internal core is still active and I²C accessible.

NCV6336 shuts internal core down when AVIN falls below UVLO.

Dynamic Voltage Scaling (DVS)

This converter supports dynamic voltage scaling (DVS) allowing the output voltage to be reprogrammed via I²C commands and provides the different voltages required by the processor. The change between set points is managed in a smooth fashion without disturbing the operation of the processor.

When programming a higher voltage, output raises with controlled dV/dt defined by DVS[1..0] bits in TIME register. When programming a lower voltage the output voltage will decrease accordingly.

The DVS step is fixed and the speed is programmable.

DVS sequence is automatically initiated by changing output voltage settings. There are two ways to change these settings:

- Directly change the active setting register value (VoutVSEL0[6..0] of PROGVSEL0 register or VoutVSEL1[6..0] of the PROGVSEL1 register) via I²C command
- Change the VSEL internal signal level by toggling VSEL pin.

The second method eliminates the I²C latency and is therefore faster.

The DVS transition mode can be changed with the DVSMODE bit in COMMAND register:

- In forced PWM mode when accurate output voltage control is needed.

Figure 37. DVS in Forced PWM Mode Diagram

- In Auto mode when output voltage has not to be discharged. Note that approximately 30 μs is needed to transition from PFM mode to PWM mode.

Figure 38. DVS in Auto Mode Diagram

Digital IO Settings

VSEL Pin

By changing VSEL pin levels, the user has a latency free way to change NCV6336 configuration: operating mode (Auto or PWM forced), the output voltage as well as enable.

Table 2. VSEL PIN PARAMETERS

Parameter VSEL Pin Can Set	REGISTER VSEL = LOW	REGISTER VSEL = HIGH
ENABLE	ENVSEL0 PROGVSEL0[7]	ENVSEL1 PROGVSEL1[7]
VOUT	VoutVSEL0[6..0]	VoutVSEL1[6..0]
OPERATING MODE (Auto / PWM Forced)	PWMVSEL0 COMMAND[7]	PWMVSEL1 COMMAND[6]

VSEL pin action can be masked by writing 0 to the VSELGT bit in the COMMAND register. In that case I²C bit corresponding to VSEL high will be taken into account.

EN Pin

The EN pin can be gated by writing the ENVSEL0 or ENVSEL1 bits of the PROGVSEL0 and PROGVSEL1 registers, depending on which register is activated by the VSEL internal signal.

Power Good Pin (Optional)

To indicate the output voltage level is established, a power good signal is available.

The power good signal is low when the DC to DC converter is off. Once the output voltage reaches 95% of the expected output level, the power good logic signal becomes high and the open drain output becomes high impedance.

During operation when the output drops below 90% of the programmed level the power good logic signal goes low (and the open drain signal transitions to a low impedance state) which indicates a power failure. When the voltage rises again to above 95% the power good signal goes high again.

During a positive DVS sequence, when target voltage is higher than initial voltage, the Power Good logic signal will be set low during output voltage ramping and transition to high once the output voltage reaches 95% of the target voltage. When the target voltage is lower than the initial voltage, Power Good pin will remain at high level during transition.

Power Good signal during normal operation can be disabled by clearing the PGDCDC bit in PGOOD register.

Power Good operation during DVS can be controlled by setting / clearing the bit PGDVS in PGOOD register

Figure 39. Power Good Signal

Power Good Delay

In order to generate a Reset signal, a delay can be programmed between the output voltage gets 95% of its final value and Power Good pin is released to high level.

The delay is set from 0 ms to 70.4 ms through the TOR[1..0] bits in the TIME register. The default delay is 0 ms.

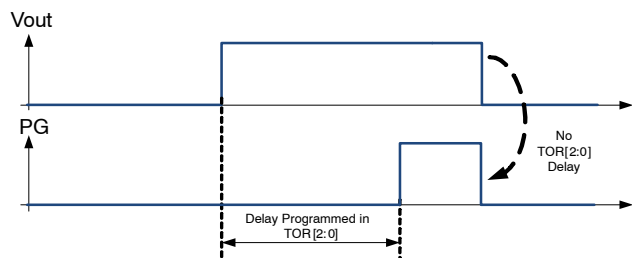

Figure 40. Power Good Operation

Interrupt Pin (Optional)

The interrupt controller continuously monitors internal interrupt sources, generating an interrupt signal when a system status change is detected (dual edge monitoring).

Table 3. INTERRUPT SOURCES

Interrupt Name	Description
TSD	Thermal Shut Down
TWARN	Thermal Warning
TPREW	Thermal Pre Warning
UVLO	Under Voltage Lock Out
IDCDC	DC to DC converter current Over / below limit
PG	Power Good

Individual bits generating interrupts will be set to 1 in the INT_ACK register (I²C read only registers), indicating the interrupt source. INT_ACK register is automatically reset by an I²C read. The INT_SEN register (read only register) contains real time indicators of interrupt sources.

All interrupt sources can be masked by writing in register INT_MSK. Masked sources will never generate an interrupt request on INTB pin.

The INTB pin is an open drain output. A non masked interrupt request will result in INTB pin being driven low.

NCV6336

When the host reads the INT_ACK registers the INTB pin is released to high impedance and the interrupt register INT_ACK is cleared.

Figure 41 is UVLO event example: INTB pin with INT_SEN/INT_MSK/INT_ACK and an I²C read access behavior.

Figure 41. Interrupt Operation Example

INT_MSK register is set to disable INTB feature by default.

Configurations

Default output voltages, enables, DCDC modes, current limit and other parameters can be factory programmed upon request. Below is the default configurations pre-defined:

Configuration	NCV6336BM – 5.0 A	NCV6336C – 5.0 A
Default I ² C address	0x1C	0x1C
PID product identification	15h	15h
RID revision identification	xxh	xxh
FID feature identification	00h	00h
Default VOUT – VSEL=1	1.20 V	1.15 V
Default VOUT – VSEL=0	1.20 V	1.15 V
Default MODE – VSEL=1	Auto mode – ON	Auto mode – ON
Default MODE – VSEL=0	Auto mode – ON	Auto mode – ON
Default IPEAK	6.8 A	6.8 A
OPN	NCV6336BMFCCT1G	NCV6336CFCCT1G
Marking	6336BM	6336CV

I²C Compatible Interface

NCV6336 can support a subset of I²C protocol Detailed below.

I²C Communication Description

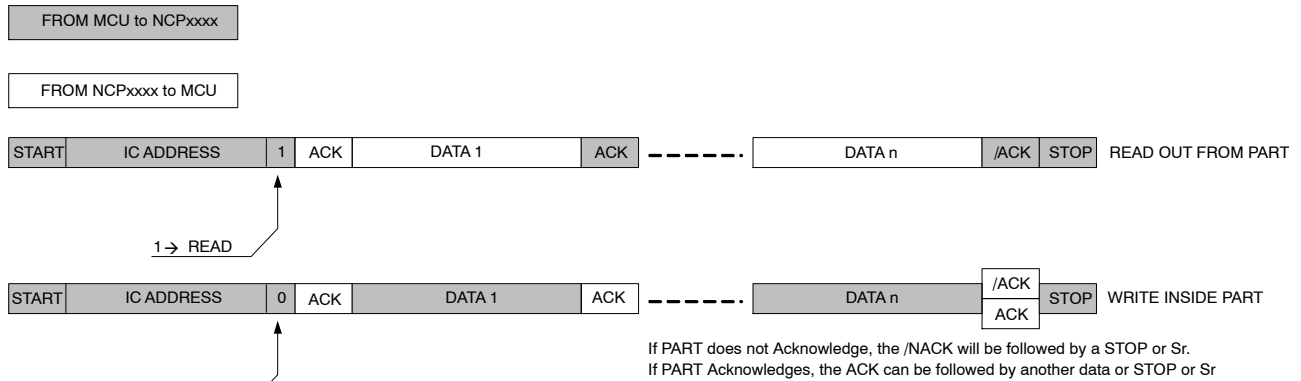

Figure 42. General Protocol Description

The first byte transmitted is the Chip address (with the LSB bit set to 1 for a read operation, or set to 0 for a Write operation). The following data will be:

- In case of a Write operation, the register address (@REG) pointing to the register we want to write in followed by the data we will write in that location. The writing process is auto-incremental, so the first data will be written in @REG, the contents of @REG are incremented and the next data byte is placed in the location pointed to by @REG + 1 ..., etc.
- In case of read operation, the NCV6336 will output the data from the last register that has been accessed by the last write operation. Like the writing process, the reading process is auto-incremental.

Read Out from Part

The Master will first make a “Pseudo Write” transaction with no data to set the internal address register. Then, a stop then start or a Repeated Start will initiate the read transaction from the register address the initial write transaction has pointed to:

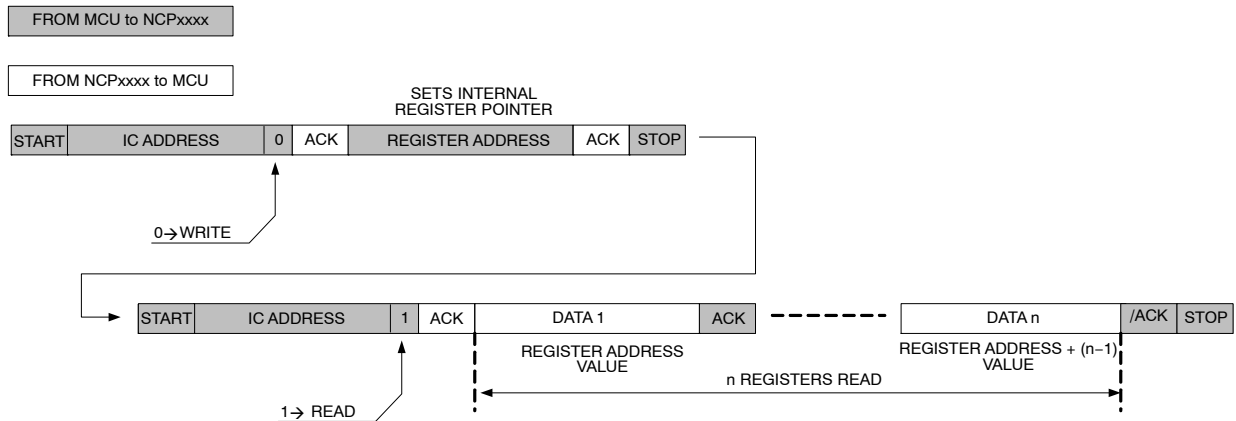

Figure 43. Read Out from Part

The first WRITE sequence will set the internal pointer to the register we want access to. Then the read transaction will start at the address the write transaction has initiated.

Transaction with Real Write then Read

With Stop Then Start

Figure 44. Write Followed by Read Transaction

Write in Part

Write operation will be achieved by only one transaction. After chip address, the MCU first data will be the internal register we want access to, then following data will be the data we want to write in Reg, Reg + 1, Reg + 2, ..., Reg + n.

Write n Registers:

Figure 45. Write in n Registers

I²C Address

NCV6336 has four available I²C address selectable by factory settings (ADD0 to ADD3). Different address settings can be generated upon request to ON Semiconductor. The default address is set to 38h / 39h since the NCV6336 supports 7-bit address only and ignores A0.

Table 4. I²C ADDRESS

I ² C Address	Hex	A7	A6	A5	A4	A3	A2	A1	A0
ADD0	W 0x20 R 0x21	0	0	1	0	0	0	0	R/W

APPLICATION INFORMATION

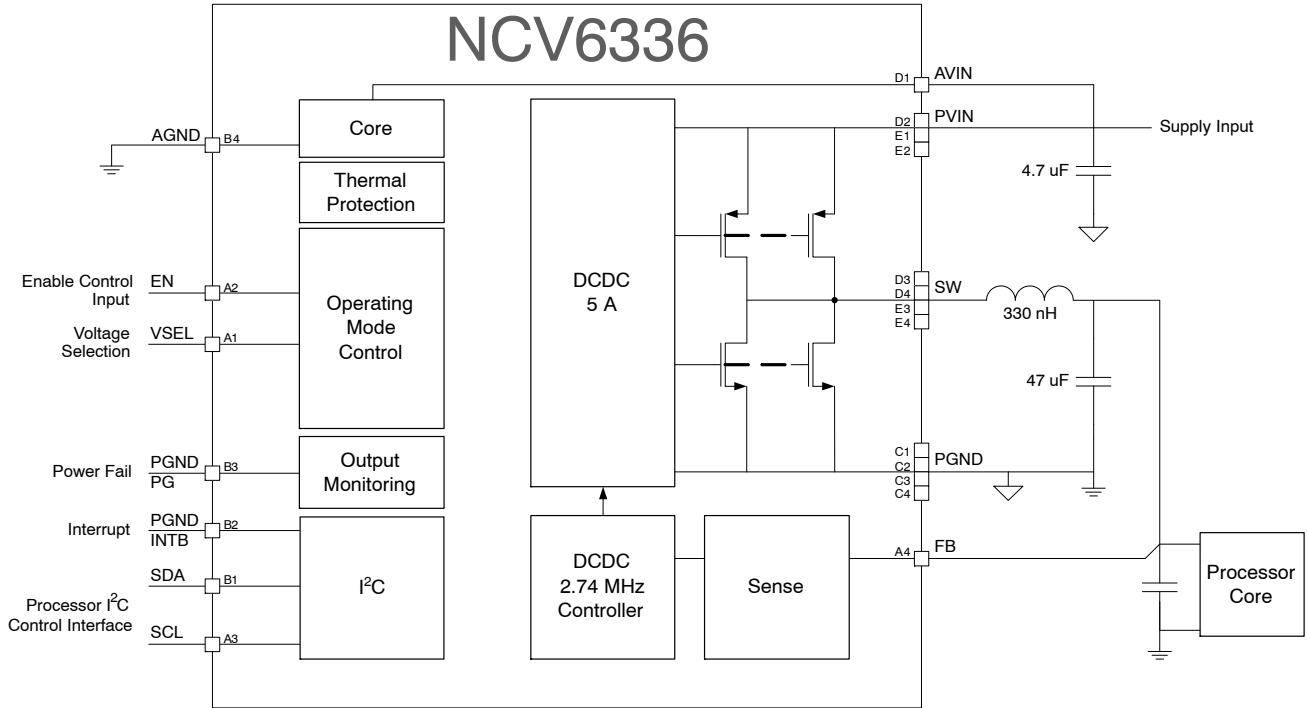

Figure 46. Typical Application Schematic

Output Filter Design Considerations

The output filter introduces a double pole in the system at a frequency of:

$$f_{LC} = \frac{1}{2 \cdot \pi \cdot \sqrt{L \cdot C}} \quad (\text{eq. 1})$$

The NCV6336 internal compensation network is optimized for a typical output filter comprising a 330 nH inductor and 47 μF capacitor as described in the basic application schematic shown in Figure 46.

Voltage Sensing Considerations

In order to regulate power supply rail, NCV6336 should sense its output voltage. Thanks to the FB pin, the IC can support two sensing methods:

- Normal case: the voltage sensing is achieved close to the output capacitor. In that case, FB is connected to the output capacitor positive terminal (voltage to regulate).
- Remote sensing: In remote sensing, the power supply rail sense is made close to the system powered by the NCV6336. The voltage to system is more accurate, since PCB line impedance voltage drop is within the regulation loop. In that case, we recommend connecting the FB pin to the system decoupling capacitor positive terminal.

Components Selection

Inductor Selection

The inductance of the inductor is determined by given peak-to-peak ripple current I_{L_PP} of approximately 20% to 50% of the maximum output current I_{OUT_MAX} for a trade-off between transient response and output ripple. The inductance corresponding to the given current ripple is:

$$L = \frac{(V_{IN} - V_{OUT}) \cdot V_{OUT}}{V_{IN} \cdot f_{SW} \cdot I_{L_PP}} \quad (\text{eq. 2})$$

The selected inductor must have high enough saturation current rating to be higher than the maximum peak current that is

$$I_{L_MAX} = I_{OUT_MAX} + \frac{I_{L_PP}}{2} \quad (\text{eq. 3})$$

The inductor also needs to have high enough current rating based on temperature rise concern. Low DCR is good for efficiency improvement and temperature rise reduction. Table 20 shows recommended.

Table 20. INDUCTOR SELECTION

Supplier	Part #	Value (μH)	Size (mm) (L x l x T) (mm)	Saturation Current Max (A)	DCR Max at 25°C (mΩ)
Cyntec	PIFE20161B-R33MS-11	0.33	2.0 x 1.6 x 1.2	4.0	33
Cyntec	PIFE25201B-R33MS-11	0.33	2.5 x 2.0 x 1.2	5.2	17

TOKO	FDSD0412-H-R33M	0.33	4.2 x 4.2 x 1.2	7.5	19
TDK	VLS252012HBX-R33M	0.33	2.5 x 2.0 x 1.2	5.3	25
TDK	SPM5030T-R35M	0.35	7.1 x 6.5 x 3.0	14.9	4

Output Capacitor Selection

The output capacitor selection is determined by output voltage ripple and load transient response requirement. For high transient load performance high output capacitor value must be used. For a given peak-to-peak ripple current I_{L_PP} in the inductor of the output filter, the output voltage ripple across the output capacitor is the sum of three components as below.

$$V_{OUT_PP} \approx V_{OUT_PP(C)} + V_{OUT_PP(ESR)} + V_{OUT_PP(ESL)} \quad (eq. 4)$$

Where $V_{OUT_PP(C)}$ is a ripple component by an equivalent total capacitance of the output capacitors, $V_{OUT_PP(ESR)}$ is a ripple component by an equivalent ESR of the output capacitors, and $V_{OUT_PP(ESL)}$ is a ripple component by an equivalent ESL of the output capacitors. In PWM operation mode, the three ripple components can be obtained by

$$V_{OUT_PP(C)} = \frac{I_{L_PP}}{8 \cdot C \cdot f_{SW}} \quad (eq. 5)$$

and

$$V_{OUT_PP(ESR)} = I_{L_PP} \cdot ESR \quad (eq. 6)$$

$$V_{OUT_PP(ESL)} = \frac{ESL}{ESL + L} \cdot V_{IN} \quad (eq. 7)$$

and the peak-to-peak ripple current is

$$I_{L_PP} = \frac{(V_{IN} - V_{OUT}) \cdot V_{OUT}}{V_{IN} \cdot f_{SW} \cdot L} \quad (eq. 8)$$

In applications with all ceramic output capacitors, the main ripple component of the output ripple is $V_{OUT_PP(C)}$. So that the minimum output capacitance can be calculated regarding to a given output ripple requirement V_{OUT_PP} in PWM operation mode.

$$C_{MIN} = \frac{I_{L_PP}}{8 \cdot V_{OUT_PP} \cdot f_{SW}} \quad (eq. 9)$$

Input Capacitor Selection

One of the input capacitor selection guides is the input voltage ripple requirement. To minimize the input voltage ripple and get better decoupling in the input power supply rail, ceramic capacitor is recommended due to low ESR and ESL. The minimum input capacitance regarding to the input ripple voltage V_{IN_PP} is

$$C_{IN_MIN} = \frac{I_{OUT_MAX} \cdot (D - D^2)}{V_{IN_PP} \cdot f_{SW}} \quad (eq. 10)$$

where

$$D = \frac{V_{OUT}}{V_{IN}} \quad (eq. 11)$$

In addition, the input capacitor needs to be able to absorb the input current, which has a RMS value of

$$I_{IN_RMS} = I_{OUT_MAX} \cdot \sqrt{D - D^2} \quad (eq. 12)$$

The input capacitor also needs to be sufficient to protect the device from over voltage spike, and normally at least 4.7 μF capacitor is required. The input capacitor should be located as close as possible to the IC. All PGNDs are connected together to the ground terminal of the input cap which then connects to the ground plane. All PVIN are connected together to the Vbat terminal of the input cap which then connects to the Vbat plane.

Electrical Layout Considerations

Good electrical layout is a key to ensuring proper operation, high efficiency, and noise reduction. Electrical layout guidelines are:

- Use wide and short traces for power paths (such as PVIN, VOUT, SW, and PGND) to reduce parasitic inductance and high-frequency loop area. It is also good for efficiency improvement.
- The device should be well decoupled by input capacitor and input loop area should be as small as possible to reduce parasitic inductance, input voltage spike, and noise emission.
- SW node should be a large copper, but compact because it is also a noise source.

- It would be good to have separated ground planes for PGND and AGND and connect the two planes at one point. Try best to avoid overlap of input ground loop and output ground loop to prevent noise impact on output regulation.
- Arrange a “quiet” path for output voltage sense, and make it surrounded by a ground plane.

Thermal Layout Considerations

Good PCB layout helps high power dissipation from a small package with reduced temperature rise. Thermal layout guidelines are:

- A four or more layers PCB board with solid ground planes is preferred for better heat dissipation.
- More free vias are welcome to be around IC to connect the inner ground layers to reduce thermal impedance.
- Use large area copper especially in top layer to help thermal conduction and radiation.
- Use two layers for the high current paths (PVIN, PGND, SW) in order to split current in two different paths and limit PCB copper self heating.

(See demo board example Figure 48)

Figure 47. Layout Recommendation

Figure 48. Demo Board Example

Input capacitor placed as close as possible to the IC.

PVIN directly connected to Cin input capacitor, and then connected to the Vin plane. Local mini planes used on the top layer (green) and layer just below top layer (yellow) with laser vias.

AVIN connected to the Vin plane just after the capacitor.

AGND directly connected to the GND plane.

PGND directly connected to Cin input capacitor, and then connected to the GND plane: Local mini planes used on the top layer (green) and layer just below top layer (yellow) with laser vias.

SW connected to the Lout inductor with local mini planes used on the top layer (green) and layer just below top layer (yellow) with laser vias.

Legend:

In green are top layer planes and wires

In yellow are layer1 plane and wires (just below top layer)

Big circles gray are normal vias

Small circles gray are top to layer1 vias
