

Integrated Driver and MOSFET

NCP252163

The NCP252163 integrates a MOSFET driver, high-side MOSFET and low-side MOSFET into a single package.

The driver and MOSFETs have been optimized for high-current DC-DC buck power conversion applications. The NCP252163 integrated solution greatly reduces package parasitics and board space compared to a discrete component solution.

Features

- Capable of Average Currents up to 60 A
- Capable of Switching at Frequencies up to 2 MHz
- Compatible with 3.3 V or 5 V PWM Input
- Responds Properly to 3-Level PWM Inputs
- Option for Zero Cross Detection with 3-Level PWM
- Internal Bootstrap Diode
- Undervoltage Lockout
- Supports Intel® Power State 4
- Thermal Warning Output
- Thermal Shutdown
- This is a Pb-Free Device

Applications

- Desktop and All-in-One Computers, V-Core and Non-V-Core DC-DC Converters
- High-Current DC-DC Point-of-Load Converters
- Small Form-Factor Voltage Regulator Modules

Theory of Operation

The NCP252163 is an integrated driver and MOSFET module designed for use in a synchronous buck converter topology. The NCP252163 supports numerous application control definitions including ZCD (Zero Current Detect) and alternately PWM Tristate control. A PWM input signal is required to control the drive signals to the high-side and low-side integrated MOSFETs.

Low-Side Driver

The low-side driver drives an internal, ground-referenced low- $R_{DS(on)}$ N-Channel MOSFET. The voltage supply for the low-side driver is internally connected to the VCCD and PGND pins.

High-Side Driver

The high-side driver drives an internal, floating low- $R_{DS(on)}$ N-channel MOSFET. The gate voltage for the high side driver is developed by a bootstrap circuit referenced to Switch Node (VSW and PHASE) pins.

The bootstrap circuit is comprised of the integrated diode and an external bootstrap capacitor and resistor. When the NCP252163 is starting up, the VSW pin is at ground, allowing the bootstrap capacitor to charge up to VCCD through the bootstrap diode (See Figure 1). When the PWM input is driven high, the high-side driver turns on the high-side MOSFET using the stored charge of the bootstrap capacitor. As the high-side MOSFET turns on, the voltage

at the VSW and PHASE pins rises. When the high-side MOSFET is fully turned on, the switch node settles to VIN and the BST pin settles to VIN + VCCD – Vdiode (excluding parasitic ringing).

Bootstrap Circuit

The bootstrap circuit relies on an external charge storage capacitor (CBST) and an integrated diode to provide current to the HS Driver. A multi-layer ceramic capacitor (MLCC) with a value greater than 100 nF should be used as the bootstrap capacitor. A 1 to 5 Ω resistor in series with the bootstrap capacitor can be used to decrease the VSW overshoot.

Power Supply Decoupling

The NCP252163 sources relatively large currents into the MOSFET gates. In order to maintain a constant and stable supply voltage (VCCD) a low-ESR capacitor should be placed near the power and ground pins. A multi-layer ceramic capacitor (MLCC) between 1 μF and 4.7 μF is typically used.

A separate supply pin (VCC) is used to power the analog and digital circuits within the driver. A 1 μF ceramic capacitor should be placed on this pin in close proximity to the NCP252163. It is good practice to separate the VCC and VCCD decoupling capacitors with a resistor (2 – 10 Ω typical) to avoid coupling driver noise to the analog and digital circuits that control the driver function (See Figure 1). It is recommended to connect the supply to VCCD and then VCC through the filter.

Safety Timer and Overlap Protection Circuit

It is important to avoid cross-conduction of the two MOSFETS which could result in a decrease in the power conversion efficiency or damage to the device.

The NCP252163 prevents cross-conduction by monitoring the status of the MOSFETS and applying the appropriate amount of non-overlap (NOL) time (the time between the turn-off of one MOSFET and the turn-on of the other MOSFET). When the PWM input pin is driven high, the gate of the low-side MOSFET (LSGATE) goes low after a propagation delay (TPWM_PD_R). The time it takes for the low-side MOSFET to turn off is dependent on the total charge on the low-side MOSFET gate.

The NCP252163 monitors the gate voltage of both MOSFETS and the switch node voltage to determine the conduction status of the MOSFETS. Once the low-side MOSFET is turned off an internal timer delays the turn-on of the high-side MOSFET. When the PWM input pin goes low, the gate of the high-side MOSFET (HSGATE) goes low after the propagation delay (TPWM_PD_F). The time to turn off the high-side MOSFET is dependent on the total gate charge of the high-side MOSFET. A timer is triggered once the high-side MOSFET stops conducting, to delay the turn-on of the low-side MOSFET.

Zero Current Detect

The Zero Current Detect PWM (ZCD_PWM) mode is enabled when SMOD# is HIGH or MID (see Tables 6 & 8).

With PWM set to > VPWM_HI, GL goes low and GH goes high after the non-overlap delay. When PWM is driven to < VPWM_HI and to > VPWM_LO, GL goes high after the non-overlap delay, and stays high for the duration of the ZCD blanking timer (TZCD_BLANK) and an 80 ns de-bounce timer. Once this timer expires, VSW is monitored for zero current detection, and GL is pulled low once zero current is detected. The threshold on VSW to determine zero current undergoes an auto-calibration cycle every time DISB# is brought from low to high. This auto-calibration cycle typically takes 25 μs to complete.

PWM Input

The PWM Input pin is a tri-state input used to control the HS MOSFET ON/OFF state. It also determines the state of the LS MOSFET. See Table 6 for logic operation. The PWM in some cases must operate with frequency programming resistances to ground. These resistances can range from 10 kΩ to 300 kΩ depending on the application. When SMOD# is set to > VSMOD#_HI or to < VSMOD#_LO, the input impedance to the PWM input is very high in order to avoid interferences with controllers that must use programming resistances on the PWM pin.

If SMOD# is set to < VSMOD#_HI and > VSMOD#_LO (Mid-State), the PWM pin undriven default voltage is set to Mid-State with internal divider resistances.

Disable Input (DISB#)

The DISB# pin is used to disable the GH to the High-Side FET to prevent power transfer. The pin has a pull-down resistance to force a disabled state when it is left unconnected. DISB# can be driven from the output of a logic device or set high with a pull-up resistance to VCC.

Table 7. UVLO/DISB# LOGIC TABLE

UVLO	DISB#	Driver State
L	X	Disabled (GH = GL = 0)
H	L	Disabled (GH = GL = 0)
H	H	Enabled (See Table 1)
H	Open	Disabled (GH = GL = 0)

VCC Undervoltage Lockout

The VCC pin is monitored by an Undervoltage Lockout Circuit (UVLO). A VCC voltage above the rising threshold enables the NCP252163.

Thermal Warning

The THWN pin is an open drain output. When the temperature of the driver exceeds T_{THWN}, the THWN pin is pulled low indicating a thermal warning. At this point, the

NCP252163

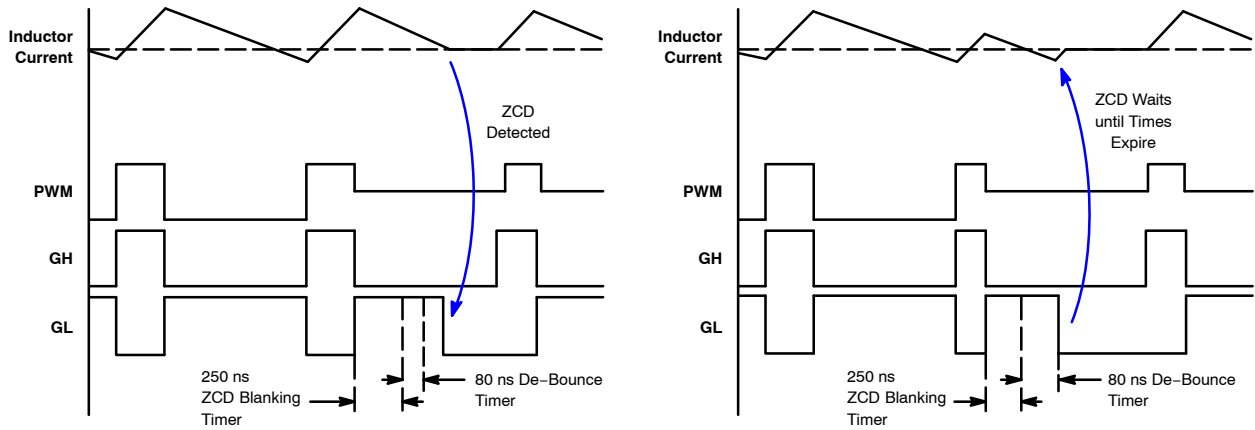

part continues to function normally. When the temperature drops T_{THWN_HYS} below T_{THWN} , the THWN pin goes high. If the driver temperature exceeds T_{THDN} , the part enters thermal shutdown and turns off both MOSFETs. Once the temperature falls T_{THDN_HYS} below T_{THDN} , the part resumes normal operation.

Skip Mode Input (SMOD#)

The SMOD# tri-state input pin has an internal pull-up resistance to VCC. When driven low, the SMOD# pin

enables the low side synchronous MOSFET to operate independently of the internal ZCD function. When the SMOD# pin is set low while PWM is in the mid-state, the low side MOSFET can be disabled to allow discontinuous mode operation.

The NCP252163 has the capability of internally connecting a resistor divider to the PWM pin. To engage ZCD, SMOD# needs to be placed into mid-state or high. While in SMOD# mid-state, the IC logic is equivalent to SMOD# being in the high state.

NOTE: If the Zero Current Detect circuit detects zero current after the ZCD Wait timer period, the GL is driven low by the Zero Current Detect signal.
If the Zero Current Detect circuit detects zero current before the ZCD Wait timer period expires, the Zero Current detect signal is ignored and the GL is driven low at the end of the ZCD Wait timer period.

NOTE: If the SMOD# input is driven low at any time after the GL has been driven high, the SMOD# Falling edge triggers the GL to go low.
If the SMOD# input is driven low while the GH is high, the SMOD# input is ignored.

Figure 25. SMOD# Timing Diagram

NCP252163

For Use with Controllers with 3-State PWM and No Zero Current Detection Capability:

Table 8. LOGIC TABLE – 3-STATE PWM CONTROLLERS WITH NO ZCD

PWM	SMOD#	GH (Not a Pin)	GL
H	H or MID	ON	OFF
M	H or MID	OFF	ZCD
L	H or MID	OFF	ON

This section describes operation with controllers that are capable of 3 states in their PWM output and relies on the NCP252163 to conduct zero current detection during discontinuous conduction mode (DCM).

The SMOD# pin needs to either be set to 5 V or left disconnected. The NCP252163 has an internal pull-down resistor that connects to VCC that sets SMOD# to the logic high state if this pin is disconnected.

To operate the buck converter in continuous conduction mode (CCM), PWM needs to switch between the logic high

and low states. To enter into DCM, PWM needs to be switched to the mid-state.

Whenever PWM transitions to mid-state, GH turns off and GL turns on. GL stays on for the duration of the de-bounce timer and ZCD blanking timers. Once these timers expire, the NCP252163 monitors the SW voltage and turns GL off when SW exceeds the ZCD threshold voltage. By turning off the LS FET, the body diode of the LS FET allows any positive current to go to zero but prevents negative current from conducting.

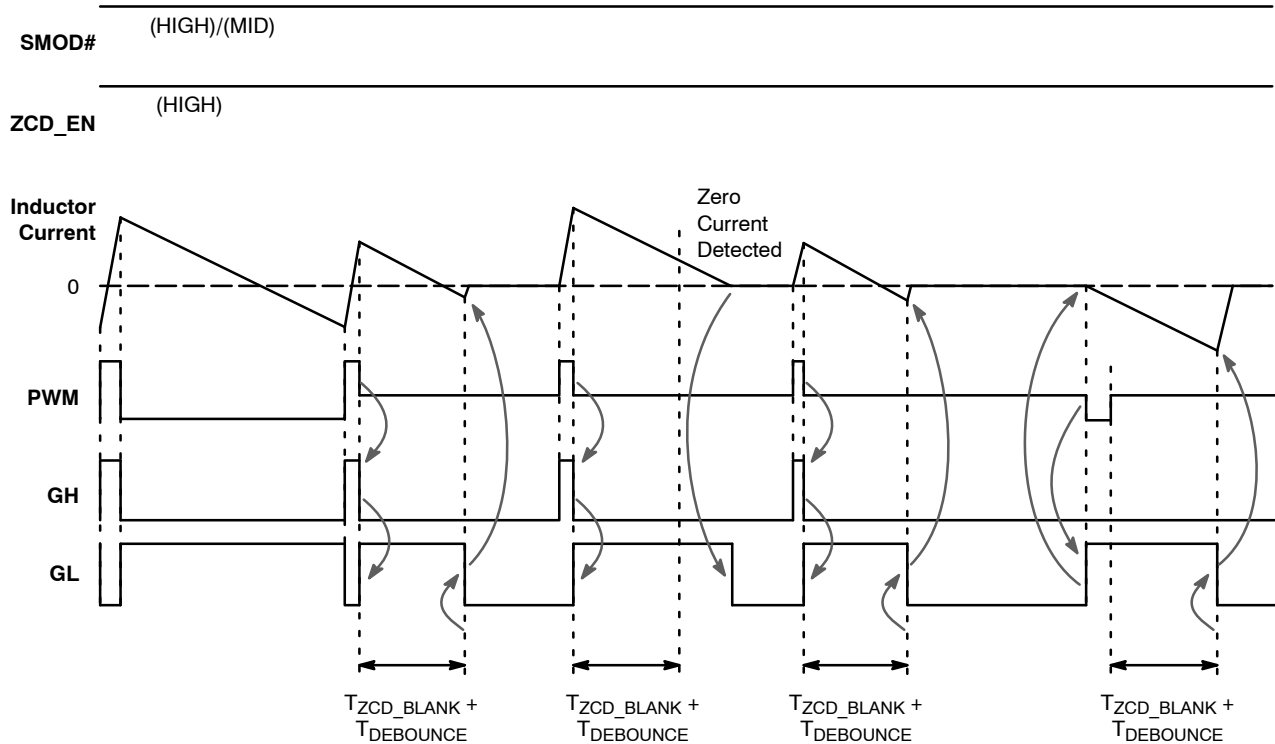

Figure 26. Timing Diagram – 3-state PWM Controller, No ZCD

NCP252163

For Use with Controllers with 3-State PWM
 Controllers Detection Capability:

Table 9. LOGIC TABLE – 3-STATE PWM CONTROLLERS WITH ZCD

PWM	SMOD#	GH (Not a Pin)	GL
H	L	ON	OFF
M	L	OFF	OFF
L	L	OFF	ON

This section describes operation with controllers that are capable of 3 PWM output levels and have zero current detection during discontinuous conduction mode (DCM).

The SMOD# pin needs to be pulled low (below V_{SMOD_LO}).

To operate the buck converter in continuous conduction mode (CCM), PWM needs to switch between the logic high

and low states. During DCM, the controller is responsible for detecting when zero current has occurred, and then notifying the NCP252163 to turn off the LS FET. When the controller detects zero current, it needs to set PWM to mid-state, which causes the NCP252163 to pull both GH and GL to their off states without delay.

onsemi and ONSEMI are trademarks of Semiconductor Components Industries, LLC dba onsemi or its subsidiaries in the United States and/or other countries. onsemi reserves the right to make changes without further notice to any products herein. onsemi makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does onsemi assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation special, consequential or incidental damages. onsemi does not convey any license under its patent rights nor the rights of others.

onsemi, **Onsemi**, and other names, marks, and brands are registered and/or common law trademarks of Semiconductor Components Industries, LLC dba "**onsemi**" or its affiliates and/or subsidiaries in the United States and/or other countries. **onsemi** owns the rights to a number of patents, trademarks, copyrights, trade secrets, and other intellectual property. A listing of **onsemi**'s product/patent coverage may be accessed at www.onsemi.com/site/pdf/Patent-Marking.pdf. **onsemi** reserves the right to make changes at any time to any products or information herein, without notice. The information herein is provided "as-is" and **onsemi** makes no warranty, representation or guarantee regarding the accuracy of the information, product features, availability, functionality, or suitability of its products for any particular purpose, nor does **onsemi** assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation special, consequential or incidental damages. Buyer is responsible for its products and applications using **onsemi** products, including compliance with all laws, regulations and safety requirements or standards, regardless of any support or applications information provided by **onsemi**. "Typical" parameters which may be provided in **onsemi** data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals" must be validated for each customer application by customer's technical experts. **onsemi** does not convey any license under any of its intellectual property rights nor the rights of others. **onsemi** products are not designed, intended, or authorized for use as a critical component in life support systems or any FDA Class 3 medical devices or medical devices with a same or similar classification in a foreign jurisdiction or any devices intended for implantation in the human body. Should Buyer purchase or use **onsemi** products for any such unintended or unauthorized application, Buyer shall indemnify and hold **onsemi** and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that **onsemi** was negligent regarding the design or manufacture of the part. **onsemi** is an Equal Opportunity/Affirmative Action Employer. This literature is subject to all applicable copyright laws and is not for resale in any manner.
